Test-Driven Development (TDD)

Test-Driven Development, or TDD, is an iterative **software development process** which uses **very short development cycles** and leverages **tests** to provide constant **feedback** to software developers.

Goal: “clean code that works”, i.e., develop better software, less stressfully.

Test-Driven Development (TDD)

Test-Driven Development, or TDD, is an iterative **software development process** which uses **very short development cycles** and leverages **tests** to provide constant **feedback** to software developers.

Goal: “clean code that works”, i.e., develop better software, less stressfully.

The “Test-Driven Development” expression is often (ab)used to talk about 2 distinct things:

- the TDD development process
- the **xUnit** family of **testing frameworks**
 - ▶ e.g., JUnit, Python’s unittest, Check, OUnit, ...

which have been designed to support the TDD development process, but can also be used when adopting different development process

xUnit

xUnit collectively refers to a set of **frameworks for automated unit testing** which share a **common test coding style**.

Each xUnit framework includes:

- test case** abstraction used to define tests

- test suite** abstraction used to organize test in test suites

- assertion API** to implement test case oracles to verify outcomes

- test fixture** mechanisms to factorize test initialization and clean up code

- test runner** end-user program to discover and (selectively) run test suites

- test result formatters** summarize test results and present them for human consumption

xUnit implementations

Testing frameworks that adhere to the xUnit paradigm exist for most languages and platforms, e.g.:¹

- SUnit (Smalltalk)
- JUnit (Java)
- CppUnit (C++)
- OUnit (OCaml)
- Test::Unit (Ruby)
- HUnit (Haskell)
- NUnit (.NET)
- unittest (Python)
- Check (C)

3 Bootstrapping TDD

Development as learning

- every software development project tries *something* that has **never been tried before**
 - ▶ otherwise you wouldn't be doing it. . .
- due to constraints, developers often use technologies they don't completely master
 - ▶ new technologies, old technologies used in new contexts, etc
- all stakeholders (developers, managers, customers) **learn as the project progresses**

Problem

As we don't know everything at the beginning, there will be **unexpected changes** during the project.

How do we cope with them?

Nested feedback loops

Idea

- 1 we use **empirical feedback** to learn about the system
- 2 we **store what we learn** in the system itself, for future use

To do so, we organize development as **nested feedback loops** with increasing time periods and scopes in the organization (file, unit, product, team, etc.), e.g.:

- pair programming period: seconds
- unit tests seconds–1 minute
- acceptance tests minutes
- daily meeting 1 day
- iterations 1 day–1 week
- releases 1 week–months

We want **feedback as quickly as possible**. If something slips through an inner loop, it will (hopefully) be caught by an outer one.

Expecting the unexpected

Practices that (empirically) help coping with unexpected changes:

- **constant testing**

- ▶ when we change something we might introduce **regressions**
- ▶ to avoid that we need to constantly test our system
- ▶ doing it manually doesn't scale ⇒ **automated testing**

- **simple design**

keep the code as simple as possible
optimize for simplicity

- ▶ as we will have to change it, we want code that is **easy to understand and modify**
- ▶ empirical studies show that **developers spend more time reading code** than writing it
- ▶ clean design doesn't come for free, to achieve it we must constantly **refactor**
- ▶ **test suites give you courage to refactor**, and apply other changes, thanks to their tight feedback loop

TDD principle

So we have test suites. Why do we need TDD?

TDD principle

So we have test suites. Why do we need TDD? Because:

- developers don't like writing tests
- testing is often seen as a 2nd class development activity

TDD principle

So we have test suites. Why do we need TDD? Because:

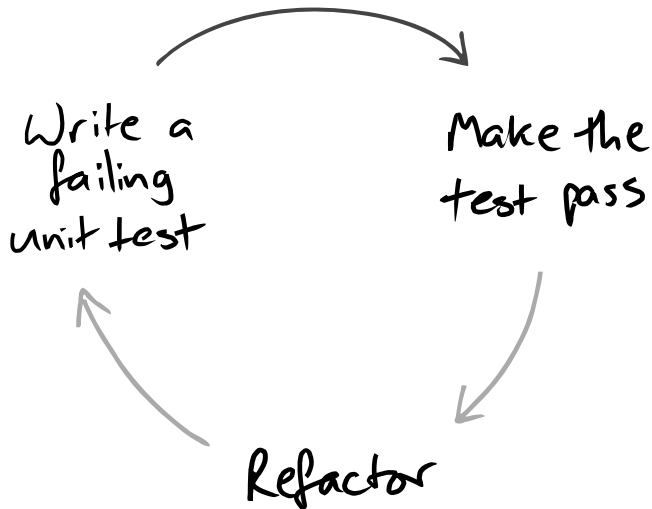

- developers don't like writing tests
- testing is often seen as a 2nd class development activity

TDD idea (i.e., a judo move on the above problem)

write tests *before* code

- don't write tests only to verify code *after* it's done
leverage **testing as a design activity**
- write tests to clarify our ideas about what the code should do
*"I was finally able to separate logical from physical design.
I'd always been told to do that but no one ever explained
how."* — Kent Beck
- write tests to get **rapid feedback about design ideas**
 - ▶ if *a test* is difficult to write, underlying design is probably wrong

TDD in a nutshell

GOOS, Figure 1.1

The TDD development cycle

- 1 **red**: write a failing test
- 2 **green**: write code that makes it pass
- 3 **refactor** the code to be as simple as possible

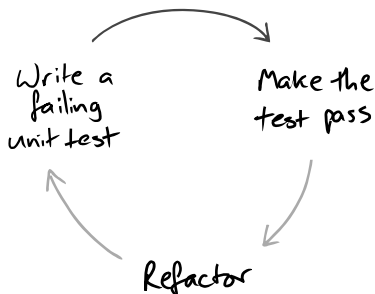

GOOS, Figure 1.1

The TDD development cycle (cont.)

- 1 **red**: write a failing test
- 2 **green**: write code that makes it pass
- 3 **refactor** the code to be as simple as possible

By **writing the test** we:

- clarify **acceptance criteria**
- are pushed to design **loosely coupled components**
 - ▶ otherwise they are difficult to test
- **document** the code, via an executable description of it
- *incrementally* build a **regression test suite**

GOOS, Figure 1.1

The TDD development cycle (cont.)

- 1 **red**: write a failing test
- 2 **green**: write code that makes it pass
- 3 **refactor** the code to be as simple as possible

By **running the test** we:

- **detect errors** when the context is fresh in our mind
- have a **measure of progress**, know when to stop (i.e., when we are “done enough”)
 - ▶ avoid over-coding, “gold plating”

GOOS, Figure 1.1

TDD golden rule

Never write a new functionality without a failing test.

Step 1 — write a failing unit test

This looks easy. But requires some care:

- write the test you want to read, ideally in 3 steps
 - 1 prepare test environment (input data and/or context)
 - 2 invoke the logic under testing
 - 3 verify that the results are correct

If it cannot be done in a few lines (ideally: 3), write helper code.

Remember: tests are documentation too.

Remember: **tests are documentation** too.

- **watch the test fail** *before* making it pass
 - ▶ otherwise you're not sure about your assumptions
 - ▶ if the test fails in unexpected ways, fix it (= the test)
 - ▶ if the **diagnostic isn't clear**, fix it

 - ▶ if the **diagnostic isn't clear**, fix it
- unit **test behavior**, not functions
 - ▶ for TDD **test coverage** is less important than readable tests

GOOS, Figure 5.2

Step 2 — make the test pass

(you won't like this)

To make the test pass we allow ourselves to **take shortcuts**.

Common strategies to make the test pass:

- **fake it** — all sorts of dirty tricks
 - ▶ e.g., return the **constant value** the test expects

To make the test pass we allow ourselves to **take shortcuts**.

Common strategies to make the test pass:

- **fake it** — all sorts of dirty tricks
 - ▶ e.g., return the **constant value** the test expects
- **obvious implementation** — just type in the “obviously right” implementation
 - ▶ it takes experience to tune your confidence
 - ▶ too confident: you will have bad surprises
 - ▶ too prudent: you'll fake it too often
 - ▶ tip: use confidence increasingly, **fall back when you get an unexpected “red bar”** (i.e., test failure)

 - ▶ tip: use confidence increasingly, **fall back when you get an unexpected “red bar”** (i.e., test failure)
- **triangulation** — when you have more than 2–3 tests that use the same implementation, factor out a common one
 - ▶ corollary: triangulation is commonly applied after several applications of the previous techniques

Step 3 — refactor

At this point: we have a test, some new code, and we are reasonably convinced that **it is that code that makes the test pass**.

We can now improve the code design, using **tests as a safety net**.

The goal of **refactoring** is to improve the design of existing code, without altering its external behavior (see Fowler 1999). We only give some of its intuitions here:

Code smells

- duplicate code
- long methods/large class
- too many parameters
- inappropriate intimacy
- Liskov principle violation
- complex conditionals
- ...

Techniques

- encapsulate field
- generalize type
- conditionals → polymorphism
- extract class/method
- rename method/field
- pull up/push down
- ...

TDD cycle — example

Goal: get a list of the elements contained in a binary tree

- 1 write a unit test that (pseudo-code)
 - 1 creates a binary tree containing the elements 2, 3, 1
 - 2 invokes a `toList` method on it
 - 3 asserts that `toList`'s return value = `[2; 3; 1]`
- Run all tests and ensures the new one *fails as we expect*
- ▶ e.g., with a compilation error due to the lack of `toList`

- ▶ e.g., with a compilation error due to the lack of `toList`

2 implement `toList`

- ▶ either by faking it: `return([2; 3; 1])`
- ▶ or by writing the implementation you consider obvious

Run all tests and ensures the new one *succeeds*

Exercise (bug fixing work-flow)

You have adopted TDD as the development process for your project. Describe the work-flow you would use to fix a bug.

Possible work-flow:

- 0 receive **bug report**
- 1 run all tests to ensure **clean slate**
- 2 create a **new test** that
 - ▶ recreates the context of the (alleged) bug
 - ▶ would succeed if the bug didn't exist
- 3 run all tests
 - ▶ new test fails → **reproducible bug**
 - ▶ new test passes → unreproducible bug → investigate with submitter

TDD cycle — exercise (cont.)

Exercise (bug fixing work-flow)

You have adopted TDD as the development process for your project. Describe the work-flow you would use to fix a bug.

Possible work-flow:

- 5 fix the bug
 - ▶ even with dirty workarounds, to ensure you've cornered it
- 6 run all tests
 - ▶ all test passes → bingo!
 - ▶ new test fails → try again (= go back to 5)
 - ▶ old tests fail → regression, try again
- 7 refactor as needed
 - ▶ from workaround, to proper fix
- 8 release fix (including the new test!)

2 Case study

3 Bootstrapping TDD

The money example

There are a several “great classics” among case studies to learn TDD and in particular its “rhythm.” Some of the most famous are:

- [The money example](#) — included in Kent Beck’s milestone book on TDD
- [The bowling game](http://www.objectmentor.com/resources/articles/xpepisode.htm) — <http://www.objectmentor.com/resources/articles/xpepisode.htm>

In the remainder we are going to discuss (some parts of) the money example. Disclaimers:

- the [rhythm](#) might seem slow at first, you will be tempted to use obvious implementation more often than in the example (which uses fake it very often)
- that’s fine, you will find your own rhythm; in the meantime starting slow will help understand the philosophy
- we will take shortcuts, check out the full example in the book

Goal: multi-currency money

Instrument	Shares	Price	Total
IBM	1000	25	25 000
GE	400	100	40 000
		Total	65 000

Instrument	Shares	Price	Total
IBM	1000	25 USD	25 000 USD
Novartis	400	150 CHF	60 000 CHF
		Total	65 000 USD

From	To	Rate
CHF	USD	1.5

Notation — To-do list

When applying TDD you will often stumble upon items you want to work on (e.g., design improvements) which you have to postpone to the appropriate phase (e.g., refactoring). To keep track of them we will use **to-do lists** like this one:

ToDo

- oh yes, we should really do this
- **but we are currently working on this**
- ~~this is done~~
- ~~this too~~

Initial to-do list for the money example:

ToDo

- $5 \text{ USD} + 10 \text{ CHF} = 10 \text{ USD}$ if rate is 2:1
- **$5 \text{ USD} * 2 = 10 \text{ USD}$**

Multiplication

Write a failing unit test:

```
@Test
```

```
public void dollarMultiplication() {  
    Dollar five = new Dollar(5);  
    five.times(2);  
    assertEquals(10, five.amount);  
}
```

Multiplication

Write a failing unit test:

```
@Test
```

```
public void dollarMultiplication() {  
    Dollar five = new Dollar(5);  
    five.times(2);  
    assertEquals(10, five.amount);  
}
```

Which doesn't compile!

- no class Dollar
- no constructor
- no method times(int)
- no field amount

Multiplication

Write a failing unit test:

```
@Test
public void dollarMultiplication() {
    Dollar five = new Dollar(5);
    five.times(2);
    assertEquals(10, five.amount);
}
```

Which doesn't compile!

- no class Dollar
- no constructor
- no method times(int)
- no field amount

That's fine! We progressed: we now have a more immediate goal to achieve (i.e., make the test compile).

Multiplication (cont.)

Let's address one compilation error at a time...

Multiplication (cont.)

Let's address one compilation error at a time...

- 1 **public class** Dollar { };
- 2 **public** Dollar(int amount) { */*empty */*};
- 3 **public void** times(int multiplier) { */*empty */*};
- 4 **public int** amount;

Multiplication (cont.)

Let's address one compilation error at a time. . .

- 1 **public class** Dollar { };
- 2 **public** Dollar(int amount) { */*empty */*};
- 3 **public void** times(int multiplier) { */*empty */*};
- 4 **public int** amount;

YAY! Now the test compiles. . . and fails with a red bar.

Progress: we now have [a measure of how far we are from success](#)—1 test is failing, we are just 1 test away from success.

Multiplication (cont.)

Let's make the bar green (you won't like this).

```
public int amount = 10; // fake it
```

The test now passes!

But that is obviously *not* the right solution so... refactor.

Multiplication (cont.)

We currently have duplication in our code, even if it's hidden:

- the test contains a $5 * 2$ multiplication
- the code contains $10 (= 5 * 2)$

we want to factor out the duplication.

```
public Dollar(int amount) {  
    this.amount = amount;  
}  
public void times(int multiplier) {  
    this.amount *= multiplier;  
}
```

Multiplication (cont.)

We currently have duplication in our code, even if it's hidden:

- the test contains a $5 * 2$ multiplication
- the code contains $10 (= 5 * 2)$

we want to factor out the duplication.

```
public Dollar(int amount) {
    this.amount = amount;
}
public void times(int multiplier) {
    this.amount *= multiplier;
}
```

ToDo

- 5 USD + 10 CHF = 10 USD if rate is 2:1
- ~~5 USD * 2 = 10 USD~~
- make amount private
- **avoid Dollar side effects**
- allow to have cents

Functional objects

```
@Test
public void dollarMultiplication() {
    Dollar five= new Dollar(5);
    five.times(2);
    assertEquals(10, five.amount);
    five.times(3);
    assertEquals(15, five.amount); // mmmmmhhhh...
}
```

Functional objects

```
@Test
public void dollarMultiplication () {
    Dollar five= new Dollar(5);
    five.times(2);
    assertEquals(10, five.amount);
    five.times(3);
    assertEquals(15, five.amount); // mmmmmmmhhhh...
}
      ↓
```

```
@Test
public void dollarMultiplication () {
    Dollar five= new Dollar(5);
    Dollar product = five.times(2);
    assertEquals(10, product.amount);
    product = five.times(3);
    assertEquals(15, product.amount); // better design!
}
```

Red bar again!

Functional objects (cont.)

Let's make it compile:

```
Dollar times(int multiplier) {  
    amount *= multiplier;  
    return null; // fake it  
}
```

test now compiles but doesn't pass

Functional objects (cont.)

Let's make it pass:

```
Dollar times(int multiplier) {  
    return new Dollar(amount * multiplier);  
}
```

Functional objects (cont.)

Let's make it pass:

```
Dollar times(int multiplier) {  
    return new Dollar(amount * multiplier);  
}
```

Green bar: YAY!

ToDo

- 5 USD + 10 CHF = 10 USD if rate is 2:1
- ~~5 USD * 2 = 10 USD~~
- make amount private
- ~~avoid Dollar-side effects~~
- allow to have cents
- **equality**

Equality

```
@Test
public void dollarsEquality() {
    assertEquals(new Dollar(5), new Dollar(5));

    // same as, but clearer than
    // assertTrue(new Dollar(5).equals(new Dollar(5)));
}
```

- the test compiles (why?)
- but fails (why?)

Equality (cont.)

```
public boolean equals(Object object) {  
    return true;  
}
```

Test passes!

Equality (cont.)

```
public boolean equals(Object object) {  
    return true;  
}
```

Test passes!

But we want a proper implementation, so let's **prove we have a bug** in the current implementation... with a test!

```
@Test  
public void dollarsInequality() {  
    assertNotEquals(new Dollar(5), new Dollar(6));  
}
```

(indeed we have a bug)

Equality (cont.)

We can now **triangulate** to a more general (and correct) solution:

```
public boolean equals(Object object) {  
    Dollar dollar = (Dollar) object;  
    return this.amount == dollar.amount;  
}
```

Green bar!!

ToDo

- 5 USD + 10 CHF = 10 USD if rate is 2:1
- make amount private
- allow to have cents
- equality
- equality against null
- equality against Object
- **5 CHF * 2 = 10 CHF**

```
@Test
public void francMultiplication() {
    Franc five = new Franc(5);
    assertEquals(new Franc(10), five.times(2));
    assertEquals(new Franc(15), five.times(3));
}
```

What's the **shortest step** which will bring us to green bar?

CHF (cont.)

Copy/paste/adapt from Dollar!

```
class Franc {
    private int amount;
    public Franc(int amount) { this.amount = amount; }
    public Franc times(int multiplier) {
        return new Franc(amount * multiplier);
    }
    public boolean equals(Object object) {
        Franc franc = (Franc) object;
        return this.amount == franc.amount;
    }
}
```

ToDo

- 5 USD + 10 CHF = 10 USD if rate is 2:1
- **Dollar/Franc duplication**
- common equals
- common times

CHF (cont.)

Refactoring to eliminate duplication:

```
class Money { protected int amount; }
class Dollar extends Money { /* ... */ }
class Franc extends Money { /* ... */ }
```

CHF (cont.)

Refactoring to eliminate duplication:

```
class Money { protected int amount; }
class Dollar extends Money { /* ... */ }
class Franc extends Money { /* ... */ }
```

```
public boolean equals(Object object) { // how about equals?
    Money dollar = (Dollar) object;    // ???
    return this.amount = dollar.amount;
}
```

ToDo

- 5 USD + 10 CHF = 10 USD if rate is 2:1
- Dollar/Franc duplication
- **common equals**
- common times

Equality redux

Bug!

```
@Test
public void equalityFrancDollar() { // this passes
    assertEquals(new Dollar(5), new Dollar(5));
    assertEquals(new Franc(7), new Franc(7));
}
```

```
@Test
public void inequalityFrancDollar() { // exception!
    assertEquals(new Dollar(5), new Franc(6));
    assertEquals(new Franc(7), new Dollar(8));
}
```

Equality redux (cont.)

```
// pull-up in class Money  
public boolean equals(Object object) {  
    Money money = (Money) object;  
    return amount == money.amount  
        && getClass().equals(money.getClass());  
}
```

ToDo

- 5 USD + 10 CHF = 10 USD if rate is 2:1
- Dollar/Franc duplication
- ~~common equals~~
- common times

Etc.

3 Bootstrapping TDD

TDD — the bigger picture

It is tempting to *use only unit tests* to implement TDD, but:

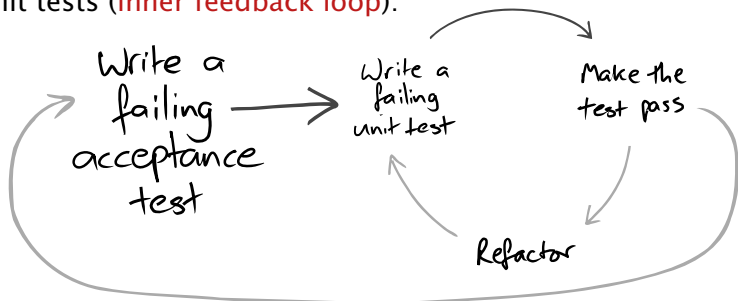

- you might end up having a lot of unused well-tested units
- you don't know where to start, nor when to stop

TDD — the bigger picture

It is tempting to **use only unit tests** to implement TDD, but:

- you might end up having a lot of unused well-tested units
- you don't know where to start, nor when to stop

That's why TDD leverages both acceptance (**outer feedback loop**) and unit tests (**inner feedback loop**):

GOOS, Figure 1.2

End-to-end testing

Acceptance tests should **exercise the system end-to-end**

- **black-box testing at system level**
 - ▶ no instantiation/invocation of internal objects
 - ▶ use the system via its interfaces (UI, external API, parsing its output and producing its inputs, etc.)

- **test both the system and its processes**
 - ▶ build
 - ▶ **deployment** in a realistic environment
 - ★ don't trust the results of acceptance tests run in development environments
 - ▶ any other qualification mechanism
 - ★ e.g., static analyses, stress testing, benchmark, etc.

Testing, quality, feedback

External quality: how well the system meets the needs of its users

Internal quality: how well the system meets the needs of its developers

- e.g., good design: **low coupling & high cohesion**
- it is often harder to push for internal than external quality, but we need to do so to cope with changes

GOOS, Figure 1.3

First feature paradox

Writing the first acceptance test at the beginning of a project is problematic:

- we want to test end-to-end the system and its processes
- but we don't have yet the tooling to make the test fail

First feature paradox

Writing the first acceptance test at the beginning of a project is problematic:

- we want to test end-to-end the system and its processes
- but we don't have yet the tooling to make the test fail

To get out of the paradox we compromise a bit, implementing a **walking skeleton** to kick start TDD.

Definition (walking skeleton)

An implementation of the smallest possible part of real functionality that we can automatically build, deploy, and test end-to-end.

To implement the walking skeleton we need to automate a lot of processes. That will force us to understand them better.

Example

The walking skeleton of a DBMS-backed web application will just show a static “Hello, World” web page.

Walking skeleton

(Some of the) tasks to be completed as part of a walking skeleton:

- create a **VCS** repository, check in the code
 - ▶ requirements: choose Version Control System, choose hosting
- **automate the build** process
 - ▶ requirement: choose build tool (e.g., Make, Maven, etc.)
 - ▶ note: “just click a button in Eclipse” ≠ automation
- **automate deployment** in a realistic environment
 - ▶ requirement: choose packaging/deployment mechanisms
- **automate test execution**
 - ▶ requirement: choose test framework
 - ▶ again: “just click a button in Eclipse” ≠ automation
- ...
- iteration 0: implement, deploy, test **first feature**

Yes, it's a lot of work!

Kick-starting TDD

GOOS, Figure 4.2

Note: “Broad-Brush Design” ≠ “Big Design Up Front (BDUF)”

TDD as a whole

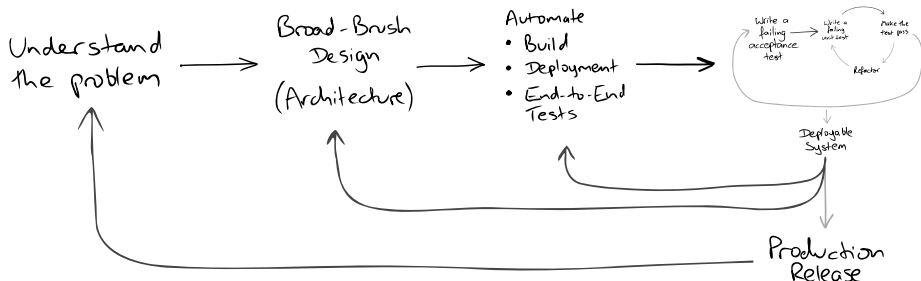

Periodically reassess both your understanding of the problem and the toolchain

TDD as a whole

Periodically reassess both your understanding of the problem and the toolchain

GOOS, Figure 4.3

Test suites organization

unit and integration test suites

- ▶ should always pass
- ▶ should run fast

acceptance test suite

- ▶ catch regressions
- ▶ should always pass
- ▶ might take longer to run

new acceptance test suite

- ▶ corresponds to work in progress
- ▶ will keep on failing during inner loop iterations
